bSign Reporting ERD

The four Salesforce objects from the 10/19 check-in, and what each one points to.

PK = primary key, FK = foreign key (a Salesforce lookup), UK = unique key. A line end with a fork is the "many" side, and that side holds the lookup. The dashed line means no lookup exists: the pipeline uses the email table to find the Account.

What each object is

OBJECT	STATUS	ONE RECORD IS	POINTS TO
`Account`	exists	One client, such as Wallace Miller.	Nothing. It is the parent.
`bSign Requester Email`	new	One email address a client sends requests from. A client with 3 emails has 3 records.	Account
`bSign Contract`	new	One contract term for a client, with start and end dates. A renewal is a new record.	Account
`bSign Usage Record`	new	One signature request. Matches one row of the Dropbox Sign extract.	Account and Contract

How a usage record gets its two lookups

A request arrives with a requester email. The pipeline finds that email in the Requester Email table, reads its Account, and sets the Account lookup. A second script finds the Contract for that Account whose start and end dates contain the request date, and sets the Contract lookup. A roll-up on Contract counts its usage records to show requests used in the term.

Raise with the team

- **Purchased quantity.** The contract fields discussed were account, start date, end date and notes. Comparing used to bought needs a quantity field, so it is shown as proposed.
- **Custom or standard Contract.** The team may reuse Salesforce's standard Contract object with a Type field set to bSign. The relationships stay the same.
- **Unique emails and unmapped emails.** Each requester email should map to exactly one Account. A request from an email not in the table needs a plan for who adds it.
